2.002 MECHANICS AND MATERIALS II SOLUTIONS FOR HOMEWORK NO. 6

Problem 1 (40 points)

Part A:

Results are shown in Figure 1. Matlab scripts for Part A and B are attached. Graphically estimated fitting constants are: $A = 9.5737 \times 10^{-12} [m/cycle(MPa\sqrt{m})^m], m = 3.17144$

Part B:

Least squares fitted constants are: $A=8.8497\times 10^{-12}[m/cycle(MPa\sqrt{m})^m],\ m=3.21473$

Part C:

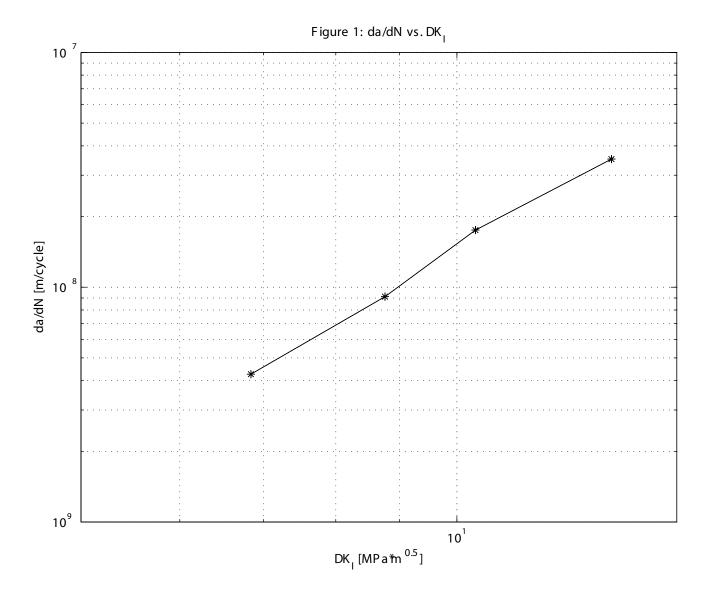

With the data for Part B, the "Paris-law" is given as following:

$$\frac{da}{dN} = A(\Delta K_I)^m = 8.8497 \times 10^{-12} (\Delta K)^{3.21473} \tag{1}$$

"Paris-law" can be rewritten as:

$$\frac{da}{dN} = \Delta a_0 \left(\frac{\Delta K_I}{\Delta K_{I0}}\right)^m \tag{2}$$

where $\Delta a_0 \equiv (\frac{da}{dN})_0$ is the corresponding reference crack growth rate, and ΔK_{I0} is a reference crack driving force. ΔK_{I0} and Δa_0 are the values of any point on the power law growth rate curve. If we choose $\Delta K_{I0} = 6.0 MPa\sqrt{m}$, the corresponding $\Delta a_0 = A \times \Delta K_{I0}^m = 2.8085 \times 10^{-9} m/cycle$, and m does not change.

```

10^p(2),p(1));
```

Problem 2 (60 points)

Part A:

Integration of the Crack-Growth equation, we get:

$$N_{a_i \to a_f} \equiv \int_0^{N_{a_i \to a_f}} = \frac{(\Delta K_{Io})^m}{(\frac{da}{dN})_o} \int_{a_i}^{a_f} \frac{da}{(Q(a)\Delta\sigma\sqrt{\pi a})^m}$$
(3)

Since Q is a constant, the above equation is reduced to :

$$N_{a_i \to a_f} = \frac{a_i}{\Delta a_o} \left(\frac{\Delta K_{Io}}{Q \Delta \sigma \sqrt{\pi a_i}}\right)^m \frac{2}{m-2} \left[1 - \left(\frac{a_i}{a_f}\right)^{\frac{(m-2)}{2}}\right]; \tag{4}$$

where a_f is a function of the maximum stress:

$$a_f = \frac{1}{\pi} \left(\frac{K_{IC}}{Q\sigma_{max}} \right)^2 \tag{5}$$

Substitution of a_f and $\Delta \sigma = \sigma_{max}$ into the expression of $N_{a_i \to a_f}$, and rearrange the equation, we get the following expression:

$$N_{a_i \to a_f} = \frac{a_i}{\Delta a_o} (\frac{\Delta K_{Io}}{\sqrt{\pi a_i}})^m \frac{2}{m-2} [(Q\sigma_{max})^{-m} - (\frac{\pi a_i}{K_{IC}^2})^{\frac{m-2}{2}} (Q\sigma_{max})^{-2}]; \tag{6}$$

In the above equation, $a_i = 3mm$, $\Delta a_o = 10^{-5}mm/cycle$, $\Delta K_{Io} = 20MPa\sqrt{m}$, and $N_{a_i \to a_f} = 100,000$. Substitution of the above numbers, we get the equation to solve for σ_{max} :

$$10^{5} = \frac{3}{10^{-5}} \left(\frac{20}{\sqrt{\pi 0.003}}\right)^{4} \frac{2}{4-2} \left\{1.12^{-4} (\sigma_{max})^{-4} - \left(\frac{\pi 0.003}{(115)^{2}} \times 1.12^{-2} (\sigma_{max})^{-2}\right)\right\}$$
(7)

N vs. σ_{max} is plotted in Figure 2. Use Newton's method to solve the above equation, and the Matlab script is attached. The result is $\sigma_{max} = 238.93 \ MPa$.

Part B:

a(n=50,000)=5.7[mm], the corresponding value of $K_I=35.8[MPa\sqrt{m}]$ and the predicted factor of safety at this point is $K_{Ic}/K_I(\sigma_{max},a(N=50,000))=115/35.8=3.2$

Part C:

The safety factor on fatigue K_{Ic}/K_I is larger than the factor on fatigue life. That is because the growth of crack length a accelerates as N increase (Figure 3). Thus, when $N = 1/2N_{critical}$, $a < 1/2a_{critical}$ and so does K_I .
